An introduction to the reshape2 package

BISC 888–1 Simon Fraser University

Sean C. Anderson sean@seananderson.ca

October 4, 2013

reshape2 is an R package written by Hadley Wickham that makes it easy to transform data between wide and long formats.

What makes data wide or long?

Wide data has a column for each variable. For example, this is wide-format data:

> head(d)

```
ozone wind temp
1 23.61538 11.622581 65.54839
2 29.44444 10.266667 79.10000
3 59.11538 8.941935 83.90323
4 59.96154 8.793548 83.96774
```

And this is long-format data:

> melt(d)

```
variable
                 value
1
      ozone 23.615385
2
      ozone 29.44444
3
      ozone 59.115385
4
      ozone 59.961538
5
       wind 11.622581
6
       wind 10.266667
7
       wind 8.941935
8
       wind 8.793548
9
       temp 65.548387
10
       temp 79.100000
11
       temp 83.903226
12
       temp 83.967742
```

Long-format data has a column for possible variable types and a column for the values of those variables. Long-format data isn't necessarily only two columns. For example, we might have ozone measurements for each day of the year. In that case, we could have another column for day. In other words, there are different levels of "longness". The ultimate shape you want to get your data into will depend on what you are doing with it.

It turns out that you need wide-format data for some types of data analysis and long-format data for others. In reality, you need long-format data much more commonly than wide-format data. For example, ggplot2 requires long-format data, plyr requires long-format data, and most modelling functions (such as lm(), glm(), and gam()) require long-format data. But people often find it easier to record their data in wide format.

The reshape2 package

reshape2 is based around two key functions: melt and cast:

melt takes wide-format data and melts it into long-format data.

cast takes long-format data and casts it into wide-format data.

Think of working with metal: if you melt metal, it drips and becomes long. If you cast it into a mould, it becomes wide.

Wide- to long-format data: the melt function

For this example we'll work with the airquality dataset that is built into R. First we'll change the column names to lower case to make them easier to work with. Then we'll look at the data:

```
> names(airquality) <- tolower(names(airquality))</pre>
> head(airquality)
  ozone solar.r wind temp month day
     41
            190 7.4
1
                        67
                                5
                                    1
2
                                    2
     36
            118 8.0
                        72
                                5
3
                                    3
     12
            149 12.6
                        74
                                5
4
                                    4
     18
            313 11.5
                        62
                                5
5
     NA
             NA 14.3
                        56
                                5
                                    5
6
     28
             NA 14.9
                        66
                                5
                                    6
```

What happens if we run the function melt with all the default argument values?

```
> aql <- melt(airquality) # [a]ir [q]uality [1]ong format
> head(aql)
```

```
variable value
1
               41
     ozone
2
               36
     ozone
3
     ozone
               12
4
               18
     ozone
5
     ozone
               NA
6
     ozone
               28
```

> tail(aql)

	variable	value
913	day	25
914	day	26
915	day	27

```
916 day 28
917 day 29
918 day 30
```

By default, melt has assumed that all columns with numeric values are variables with values. Often this is what you want. Maybe here we want to know the values of ozone, solar.r, wind, and temp for each month and day. We can do that with melt by telling it that we want month and day to be "ID variables". ID variables are the variables that identify individual rows of data.

```
> agl <- melt(airquality, id.vars = c("month", "day"))</pre>
> head(aql)
  month day variable value
1
      5
           1
                 ozone
                           41
2
      5
           2
                           36
                 ozone
3
      5
           3
                           12
                 ozone
4
      5
           4
                 ozone
                           18
      5
5
           5
                           NA
                 ozone
6
      5
           6
                           28
                 ozone
```

What if we wanted to control the column names in our long-format data? melt lets us set those too all in one step:

```
> aql <- melt(airquality, id.vars = c("month", "day"),
+ variable.name = "climate_variable", value.name = "climate_value")
> head(aql)
```

	month	day	<pre>climate_variable</pre>	<pre>climate_value</pre>
1	5	1	ozone	41
2	5	2	ozone	36
3	5	3	ozone	12
4	5	4	ozone	18
5	5	5	ozone	NA
6	5	6	ozone	28

Long- to wide-format data: the cast functions

Whereas going from wide- to long-format data is pretty straightforward, going from long- to wide-format data can take a bit more thought. It usually involves some head scratching and some trial and error for all but the simplest cases. Let's go through some examples.

In reshape2 there are multiple cast functions. Since you will most commonly work with data.frame objects, we'll explore the dcast function. (There is also acast to return a vector, matrix, or array.)

Let's take the long-format airquality data and cast it into some different wide formats. To start with, we'll recover the same format we started with and compare the two.

dcast uses a formula to describe the shape of the data. The arguments on the left refer to the ID variables and the arguments on the right refer to the measured variables. Coming up with the right formula can take some trial and error at first. So, if you're stuck don't feel bad about just experimenting with formulas. There are usually only so many ways you can write the formula.

Here, we need to tell dcast that month and day are the ID variables (we want a column for each) and that variable describes the measured variables. Since there is only one remaining column, dcast will figure out that it contains the values themselves. We could explicitly declare this with value.var. (And in some cases it will be necessary to do so.)

```
> agl <- melt(airquality, id.vars = c("month", "day"))</pre>
> head(agl)
  month day variable value
1
      5
           1
                 ozone
2
      5
           2
                           36
                 ozone
3
      5
           3
                           12
                 ozone
4
      5
           4
                 ozone
                           18
5
      5
           5
                           NA
                 ozone
6
      5
           6
                 ozone
                           28
```

> aqw <- dcast(aql, month + day ~ variable) # [a]ir [q]uality [w]ide

> aqw <- dcast(aql, month + day ~ variable, value.var = "value") # same thing
> head(aqw)

```
month day ozone solar.r wind temp
1
      5
          1
               41
                       190 7.4
                                  67
2
      5
          2
               36
                       118 8.0
                                  72
3
      5
          3
               12
                       149 12.6
                                  74
4
      5
          4
                       313 11.5
               18
                                  62
5
      5
          5
               NA
                       NA 14.3
                                  56
6
      5
          6
               28
                        NA 14.9
                                  66
```

> head(airquality) # original data

	ozone	${\tt solar.r}$	wind	temp	month	day
1	41	190	7.4	67	5	1
2	36	118	8.0	72	5	2
3	12	149	12.6	74	5	3
4	18	313	11.5	62	5	4
5	NA	NA	14.3	56	5	5
6	28	NA	14.9	66	5	6

So, besides re-arranging the columns, we've recovered our original data.

If it isn't clear to you what just happened there, then have a look at Figure 1.

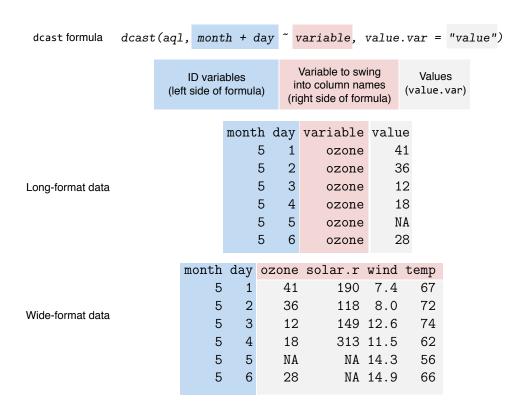

Figure 1: An illustration of the dcast function. The blue shading indicates ID variables that we want to represent individual rows. The red shading represents variable names that we want to swing into column names. The grey shading represents the data values that we want to fill in the cells with.

One confusing "mistake" you might make is casting a dataset in which there is more than one value per data cell. For example, this time we won't include day as an ID variable:

> dcast(aql, month ~ variable)

	${\tt month}$	ozone	${\tt solar.r}$		-
1	5	31	31	31	31
2	6	30	30		
3	7	31	31	31	31
4	8	31	31	31	31
5	9	30	30	30	30

When you run this in R, you'll notice the warning message:

Aggregation function missing: defaulting to length

And if you look at the output, the cells are filled with the number of data rows for each month-climate combination. The numbers we're seeing are the number of days recorded in each month. When you cast your data and there are multiple values per cell, you also need to tell dcast how to aggregate the data. For example, maybe you want to take the mean, or the median, or the sum. Let's try the last example, but this time we'll take the mean of the climate values. We'll also pass the option na.rm = TRUE through the ... argument to remove NA values. (The ... let's you pass on additional arguments to your fun.aggregate function, here mean.

> dcast(agl, month ~ variable, fun.aggregate = mean, na.rm = TRUE)

```
    month
    ozone
    solar.r
    wind
    temp

    1
    5
    23.61538
    181.2963
    11.622581
    65.54839

    2
    6
    29.44444
    190.1667
    10.266667
    79.10000

    3
    7
    59.11538
    216.4839
    8.941935
    83.90323

    4
    8
    59.96154
    171.8571
    8.793548
    83.96774

    5
    9
    31.44828
    167.4333
    10.180000
    76.90000
```

Unlike melt, there are some other fancy things you can do with dcast that I'm not covering here. It's worth reading the help file ?dcast. For example, you can compute summaries for rows and columns, subset the columns, and fill in missing cells in one call to dcast.

Additional help

```
Read the package help:
help(package = "reshape2")

See the reshape2 website:
http://had.co.nz/reshape/

And read the paper on reshape:
Wickham, H. (2007). Reshaping data with the reshape package. 21(12):1-20.
http://www.jstatsoft.org/v21/i12
(But note that the paper is written for the reshape package not the reshape2 package.)
```
